Package: piar (via r-universe)

July 18, 2024

Title Price Index Aggregation

Version 0.8.0

Description Most price indexes are made with a two-step procedure, where period-over-period elemental indexes are first calculated for a collection of elemental aggregates at each point in time, and then aggregated according to a price index aggregation structure. These indexes can then be chained together to form a time series that gives the evolution of prices with respect to a fixed base period. This package contains a collection of functions that revolve around this work flow, making it easy to build standard price indexes, and implement the methods described by Balk (2008, ISBN:978-1-107-40496-0), von der Lippe (2001, ISBN:3-8246-0638-0), and the CPI manual (2020, ISBN:978-1-51354-298-0) for bilateral price indexes.

2 aggregate.piar_index

Contents

```
40
```

Description

Aggregate elemental price indexes with a price index aggregation structure.

Usage

Index

```
## S3 method for class 'chainable_piar_index'
aggregate(
   x,
   pias,
   ...,
```

aggregate.piar_index 3

```
na.rm = FALSE,
contrib = TRUE,
r = 1,
include_ea = TRUE
)

## S3 method for class 'direct_piar_index'
aggregate(
    x,
    pias,
    ...,
    na.rm = FALSE,
    contrib = TRUE,
    r = 1,
    include_ea = TRUE
)
```

Arguments

X	A price index, usually made by elemental_index().
pias	A price index aggregation structure or something that can be coerced into one. This can be made with aggregation_structure().
	Not currently used.
na.rm	Should missing values be removed? By default, missing values are not removed. Setting na.rm = TRUE is equivalent to overall mean imputation.
contrib	Aggregate percent-change contributions in x (if any)?
r	Order of the generalized mean to aggregate index values. 0 for a geometric index (the default for making elemental indexes), 1 for an arithmetic index (the default for aggregating elemental indexes and averaging indexes over subperiods), or -1 for a harmonic index (usually for a Paasche index). Other values are possible; see gpindex::generalized_mean() for details.
include_ea	Should indexes for the elemental aggregates be included along with the aggregated indexes? By default, all index values are returned.

Details

The aggregate() method loops over each time period in x and

- aggregates the elemental indexes with gpindex::generalized_mean(r)() for each level of pias;
- 2. aggregates percent-change contributions for each level of pias (if there are any and contrib = TRUE);
- 3. price updates the weights in pias with gpindex::factor_weights(r)() (only for period-over-period elemental indexes).

The result is a collection of aggregated period-over-period indexes that can be chained together to get a fixed-base index when x are period-over-period elemental indexes. Otherwise, when x are fixed-base elemental indexes, the result is a collection of aggregated fixed-base (direct) indexes.

By default, missing elemental indexes will propagate when aggregating the index. Missing elemental indexes can be due to both missingness of these values in x, and the presence of elemental aggregates in pias that are not part of x. Setting na.rm = TRUE ignores missing values, and is equivalent to parental (or overall mean) imputation. As an aggregated price index generally cannot have missing values (for otherwise it can't be chained over time and weights can't be price updated), any missing values for a level of pias are removed and recursively replaced by the value of its immediate parent.

In most cases aggregation is done with an arithmetic mean (the default), and this is detailed in chapter 8 (pp. 190–198) of the CPI manual (2020). Aggregating with a non-arithmetic mean follows the same steps, except that the elemental indexes are aggregated with a mean of a different order (e.g., harmonic for a Paasche index), and the method for price updating the weights is slightly different. Note that, because aggregation is done with a generalized mean, the resulting index is consistent-in-aggregation at each point in time.

Aggregating percent-change contributions uses the method in chapter 9 of the CPI manual (equations 9.26 and 9.28) when aggregating with an arithmetic mean. With a non-arithmetic mean, arithmetic weights are constructed using <code>gpindex::transmute_weights(r, 1)()</code> in order to apply this method.

There may not be contributions for all prices relatives in an elemental aggregate if the elemental indexes are built from several sources (as with merge()). In this case the contribution for a price relative in the aggregated index will be correct, but the sum of all contributions will not equal the change in the value of the index. This can also happen when aggregating an already aggregated index in which missing index values have been imputed (i.e., when na.rm = TRUE and contrib = FALSE).

Value

An aggregate price index that inherits from the class of x.

Note

For large indexes it can be much faster to turn the aggregation structure into an aggregation matrix with as.matrix(), then aggregate elemental indexes as a matrix operation when there are no missing values. See the examples for details.

```

aggregation_structure 5

Examples

```
prices <- data.frame(
    rel = 1:8,
    period = rep(1:2, each = 4),
    ea = rep(letters[1:2], 4)
)

# A two-level aggregation structure

pias <- aggregation_structure(
    list(c("top", "top", "top"), c("a", "b", "c")), 1:3
)

# Calculate Jevons elemental indexes

(elemental <- with(prices, elemental_index(rel, period, ea)))

# Aggregate (note the imputation for elemental index 'c')

(index <- aggregate(elemental, pias, na.rm = TRUE))

# Aggregation can equivalently be done as matrix multiplication
as.matrix(pias) %*% as.matrix(chain(index[letters[1:3]]))</pre>
```

aggregation_structure Make a price index aggregation structure

Description

Create a price index aggregation structure from a hierarchical classification and aggregation weights that can be used to aggregate elemental indexes.

Usage

```
aggregation_structure(x, weights = NULL)
```

Arguments

Х

A list of character vectors that give the codes/labels for each level of the classification, ordered so that moving down the list goes down the hierarchy. The last vector gives the elemental aggregates, which should have no duplicates. All vectors should be the same length, without NAs, and there should be no duplicates across different levels of x.

weights

A numeric vector of aggregation weights for the elemental aggregates (i.e., the last vector in x), or something that can be coerced into one. The default is to give each elemental aggregate the same weight.

Value

A price index aggregation structure of class piar_aggregation_structure. This is a list-S3 class with the following components.

child	A nested list that gives the positions of the immediate children for each node in each level of the aggregation structure above the terminal nodes.
parent	A list that gives the position of the immediate parent for each node of the aggregation structure below the initial nodes.
levels	A list of character vectors that give the levels of x.
weights	A vector giving the weight for each elemental aggregate.

Warning

The aggregation_structure() function does its best to check its arguments, but there should be no expectation that the result of aggregation_structure() will make any sense if x does not represent a nested hierarchy.

   aggregation_structure(expand_classification(ea), weight)
)
```

```
as.data.frame.piar_index
```

Coerce an index into a tabular form

Description

Turn an index into a data frame or a matrix.

Usage

```
## S3 method for class 'piar_index'
as.data.frame(x, ..., stringsAsFactors = FALSE)
## S3 method for class 'piar_index'
as.matrix(x, ...)
```

Arguments

Value

```
as.data.frame() returns a data frame with three columns: period, level, and value.
as.matrix() returns a matrix with a row for each level and a column for each time period.
```

See Also

```
as_index() to coerce a matrix/data frame of index values into an index object.

Other index methods: [.piar_index(), aggregate.piar_index(), chain(), contrib(), head.piar_index(),
is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(),
stack.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index <- as_index(matrix(1:6, 2))
as.data.frame(index)
as.matrix(index)</pre>
```

```
as.matrix.piar_aggregation_structure
```

Coerce an aggregation structure into a tabular form

Description

Coerce a price index aggregation structure into an aggregation matrix, or a data frame.

Usage

```
## S3 method for class 'piar_aggregation_structure'
as.matrix(x, ..., sparse = FALSE)
## S3 method for class 'piar_aggregation_structure'
as.data.frame(x, ..., stringsAsFactors = FALSE)
```

Arguments

```
x A price index aggregation structure, as made by aggregation_structure().
... Not currently used.
sparse Should the result be a sparse matrix from Matrix? This is faster for large aggregation structures. The default returns an ordinary dense matrix.
stringsAsFactors
See as.data.frame().
```

Value

as.matrix() represents an aggregation structure as a matrix, such that multiplying with a (column) vector of elemental indexes gives the aggregated index.

as.data.frame() takes an aggregation structure and returns a data frame that could have generated it, with columns level1, level2, ..., ea, and weight.

See Also

```
as_aggregation_structure() for coercing into an aggregation structure.
```

Other aggregation structure methods: levels.piar_aggregation_structure(), update.piar_aggregation_structure weights.piar_aggregation_structure()

Examples

```
# A simple aggregation structure
       1
       11
                     12
# |---+
            112
                     121
# 111
# (1)
            (3)
                     (4)
aggregation_weights <- data.frame(</pre>
 level1 = c("1", "1", "1"),
level2 = c("11", "11", "12"),
ea = c("111", "112", "121"),
  weight = c(1, 3, 4)
)
pias <- as_aggregation_structure(aggregation_weights)</pre>
as.matrix(pias)
all.equal(as.data.frame(pias), aggregation_weights)
```

```
as\_aggregation\_structure
```

Coerce to an aggregation structure

Description

Coerce an object into an aggregation structure object.

Usage

```
as_aggregation_structure(x, ...)
## Default S3 method:
as_aggregation_structure(x, weights = NULL, ...)
## S3 method for class 'data.frame'
as_aggregation_structure(x, ...)
## S3 method for class 'matrix'
as_aggregation_structure(x, ...)
```

Arguments

x An object to coerce into an aggregation structure.

. . . Further arguments passed to or used by methods.

weights

A numeric vector of aggregation weights for the elemental aggregates. The default is to give each elemental aggregate the same weight.

Details

The default method attempts to coerce x into a list prior to calling aggregation_structure().

The data frame and matrix methods treat x as a table with a row for each elemental aggregate, a column of labels for each level in the aggregation structure, and a column of weights for the elemental aggregates.

Value

A price index aggregation structure that inherits from piar_aggregation_structure.

See Also

as.matrix() and as.data.frame() for coercing an aggregation structure into a tabular form.

```
# A simple aggregation structure
#
       |----|
#
      11
                   12
  |---+---|
                   # 111
                   121
           112
# (1)
           (3)
                   (4)
aggregation_weights <- data.frame(</pre>
  level1 = c("1", "1", "1"),
  level2 = c("11", "11", "12"),
  ea = c("111", "112", "121"),
  weight = c(1, 3, 4)
pias <- aggregation_structure(</pre>
  aggregation_weights[1:3],
  weights = aggregation_weights[[4]]
)
all.equal(
  pias,
  as_aggregation_structure(aggregation_weights)
)
all.equal(
  pias,
  as_aggregation_structure(as.matrix(aggregation_weights))
```

as_index 11

as_index

Coerce to a price index

Description

Coerce pre-computed index values into an index object.

Usage

```
as_index(x, ...)
## Default S3 method:
as_index(x, ..., chainable = TRUE)
## S3 method for class 'matrix'
as_index(x, ..., chainable = TRUE)
## S3 method for class 'data.frame'
as_index(x, ..., chainable = TRUE)
## S3 method for class 'chainable_piar_index'
as_index(x, ..., chainable = TRUE)
## S3 method for class 'direct_piar_index'
as_index(x, ..., chainable = FALSE)
```

Arguments

x An object to coerce into a price index.

... Further arguments passed to or used by methods.

chainable Are the index values in x period-over-period indexes, suitable for a chained cal-

culation (the default)? This should be FALSE when x is a fixed-base (direct)

index.

Details

Numeric matrices are coerced into an index object by treating each column as a separate time period, and each row as a separate level of the index (e.g., an elemental aggregate). Column names are used to denote time periods, and row names are used to denote levels (so they must be unique). This essentially reverses calling as.matrix() on an index object. If a dimension is unnamed, then it is given a sequential label from 1 to the size of that dimension. The default method coerces x to a matrix prior to using the matrix method.

The data frame method for as_index() is best understood as reversing the effect of as.data.frame() on an index object. It constructs a matrix by taking the levels of x[[1]] as columns and the levels of x[[2]] as rows (coercing to a factor if necessary). It then populates this matrix with the corresponding values in x[[3]], and uses the matrix method for as_index().

12 chain

If x is a period-over-period index then it is returned unchanged when chainable = TRUE and chained otherwise. Similarly, if x is a fixed-base index then it is returned unchanged when chainable = FALSE and unchain otherwise.

Value

as_index() returns a price index that inherits from piar_index. If chainable = TRUE then this is a period-over-period price index that also inherits from chainable_piar_index; otherwise, it is a fixed-base index that inherits from direct_piar_index.

See Also

as.matrix() and as.data.frame() for coercing an index into a tabular form.

Examples

```
prices <- data.frame(
  rel = 1:8,
  period = rep(1:2, each = 4),
  ea = rep(letters[1:2], 4)
)

index <- with(prices, elemental_index(rel, period, ea))

all.equal(as_index(as.data.frame(index)), index)
all.equal(as_index(as.matrix(index)), index)</pre>
```

chain

Chain and rebase a price index

Description

Chain a period-over-period index by taking the cumulative product of its values to turn it into a fixed-base (direct) index.

Unchain a fixed-base index by dividing its values for successive periods to get a period-over-period index.

Rebase a fixed-base index by dividing its values with the value of the index in the new base period.

Usage

```
chain(x, ...)
## Default S3 method:
chain(x, ...)
## S3 method for class 'chainable_piar_index'
chain(x, link = rep(1, nlevels(x)), ...)
```

chain 13

```
unchain(x, ...)
## Default S3 method:
unchain(x, ...)
## S3 method for class 'direct_piar_index'
unchain(x, base = rep(1, nlevels(x)), ...)
rebase(x, ...)
## Default S3 method:
rebase(x, ...)
## S3 method for class 'direct_piar_index'
rebase(x, base = rep(1, nlevels(x)), ...)
```

Arguments

x A price index, as made by, e.g., elemental_index().

... Further arguments passed to or used by methods.

link A numeric vector, or something that can coerced into one, of link values for each

level in x. The default is a vector of 1s so that no linking is done.

base A numeric vector, or something that can coerced into one, of base-period index

values for each level in x. The default is a vector of 1s so that the base period remains the same. If base is a length-one character vector giving a time period of x then the index values for this time period are used as the base-period values.

Details

The default methods attempt to coerce x into an index with as_index() prior to chaining/unchaining/rebasing.

Chaining an index takes the cumulative product of the index values for each level; this is roughly the same as t(apply(as.matrix(x), 1, cumprod)) * link. Unchaining does the opposite, so these are inverse operations. Note that unchaining a period-over-period index does nothing, as does chaining a fixed-base index.

Rebasing a fixed-base index divides the values for each level of this index by the corresponding values for each level in the new base period. It's roughly the same as as.matrix(x) / base. Like unchaining, rebasing a period-over-period index does nothing.

Percent-change contributions are removed when chaining/unchaining/rebasing an index as it's not usually possible to update them correctly.

Value

```
chain() and rebase() return a fixed-base index that inherits from direct_piar_index. unchain() returns a period-over-period index that inherits from chainable_piar_index.
```

14 contrib

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index <- as_index(matrix(1:9, 3))

# Make period 0 the fixed base period
chain(index)

# Chaining and unchaining reverse each other
all.equal(index, unchain(chain(index)))

# Change the base period to period 2 (note the
# loss of information for period 0)
index <- chain(index)
rebase(index, index[, 2])</pre>
```

contrib

Extract percent-change contributions

Description

Extract a matrix of percent-change contributions from a price index.

Usage

```
contrib(x, ...)
## S3 method for class 'piar_index'
contrib(x, level = levels(x)[1L], period = time(x), ..., pad = 0)
```

Arguments

X	A price index, as made by, e.g., elemental_index().
	Further arguments passed to or used by methods.
level	The level of an index for which percent-change contributions are desired, defaulting to the first level (usually the top-level for an aggregate index).
period	The time periods for which percent-change contributions are desired, defaulting to all time periods.
pad	A numeric value to pad contributions so that they fit into a rectangular array when products differ over time. The default is 0.

Value

A matrix of percent-change contributions with a column for each period and a row for each product (sorted) for which there are contributions in level. Contributions are padded with pad to fit into a rectangular array when products differ over time.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

```
prices <- data.frame(</pre>
  rel = 1:8,
  period = rep(1:2, each = 4),
  ea = rep(letters[1:2], 4)
)
index <- with(</pre>
  prices,
  elemental_index(rel, period, ea, contrib = TRUE)
pias <- aggregation_structure(</pre>
 list(c("top", "top", "top"), c("a", "b", "c")), 1:3
index <- aggregate(index, pias, na.rm = TRUE)</pre>
# Percent-change contributions for the top-level index
contrib(index)
# Calculate EA contributions for the chained index
library(gpindex)
arithmetic_contributions(
  as.matrix(chain(index))[c("a", "b", "c"), 2],
  weights(pias)
)
```

Description

Compute period-over-period (chainable) or fixed-base (direct) elemental price indexes, with optional percent-change contributions.

Usage

```
elemental_index(x, ...)
## Default S3 method:
elemental_index(x, ...)
## S3 method for class 'numeric'
elemental_index(
  х,
 period = gl(1, length(x)),
 ea = gl(1, length(x)),
 weights = NULL,
  chainable = TRUE,
  na.rm = FALSE,
  contrib = FALSE,
  r = 0
)
```

Arguments

ea

weights

chainable

na.rm

contrib

X	Period-over-period or fixed-base price relatives. Currently there is only a method for numeric vectors; these can be made with price_relative().
	Further arguments passed to or used by methods.
period	A factor, or something that can be coerced into one, giving the time period associated with each price relative in x. The ordering of time periods follows

of the levels of period, to agree with cut(). The default assumes that all price relatives belong to one time period.

A factor, or something that can be coerced into one, giving the elemental aggregate associated with each price relative in x. The default assumes that all price relatives belong to one elemental aggregate.

A numeric vector of weights for the price relatives in x, or something that can be coerced into one. The default is equal weights.

> Are the price relatives in x period-over-period relatives that are suitable for a chained calculation (the default)? This should be FALSE when x contains fixed-

base relatives.

Should missing values be removed? By default, missing values are not removed. Setting na.rm = TRUE is equivalent to overall mean imputation.

Should percent-change contributions be calculated? The default does not calculate contributions.

r

Order of the generalized mean to aggregate price relatives. 0 for a geometric index (the default for making elemental indexes), 1 for an arithmetic index (the default for aggregating elemental indexes and averaging indexes over subperiods), or -1 for a harmonic index (usually for a Paasche index). Other values are possible; see gpindex::generalized_mean() for details.

Details

When supplied with a numeric vector, elemental_index() is a simple wrapper that applies gpindex::generalized_mean() and gpindex::contributions(r)() (if contrib = TRUE) to x and weights grouped by ea and period. That is, for every combination of elemental aggregate and time period, elemental_index() calculates an index based on a generalized mean of order r and, optionally, percent-change contributions. The default (r = 0 and no weights) makes Jevons elemental indexes. See chapter 8 (pp. 175–190) of the CPI manual (2020) for more detail about making elemental indexes, and chapter 5 of Balk (2008).

The default method simply coerces x to a numeric vector prior to calling the method above.

Names for x are used as product names when calculating percent-change contributions. Product names should be unique within each time period, and, if not, are passed to make.unique() with a warning. If x has no names then elements of x are given sequential names within each elemental aggregate.

The interpretation of the index depends on how the price relatives in x are made. If these are period-over-period relatives, then the result is a collection of period-over-period (chainable) elemental indexes; if these are fixed-base relatives, then the result is a collection of fixed-base (direct) elemental indexes. For the latter, chainable should be set to FALSE so that no subsequent methods assume that a chained calculation should be used.

By default, missing price relatives in x will propagate throughout the index calculation. Ignoring missing values with na.rm = TRUE is the same as overall mean (parental) imputation, and needs to be explicitly set in the call to elemental_index(). Explicit imputation of missing relatives, and especially imputation of missing prices, should be done prior to calling elemental_index().

Indexes based on nested generalized means, like the Fisher index (and superlative quadratic mean indexes more generally), can be calculated by supplying the appropriate weights with <code>gpindex::nested_transmute()</code>; see the example below. It is important to note that there are several ways to make these weights, and this affects how percent-change contributions are calculated.

Value

A price index that inherits from piar_index. If chainable = TRUE then this is a period-over-period index that also inherits from chainable_piar_index; otherwise, it is a fixed-based index that inherits from direct_piar_index.

  elemental_index(
    rel, period, ea,
    fw(rel, group = interaction(period, ea)),
    r = 1
  )
)
```

expand_classification 19

expand_classification Expand a hierarchical classification

Description

Expand a character representation of a hierarchical classification to make a price index aggregation structure. Expanded classifications be interacted together to get all combinations of aggregation structures.

Usage

```
expand_classification(x, width = 1L)
interact_classifications(..., sep = ":")
```

Arguments

X	A character vector, or something that can be coerced into one, of codes/labels for a specific level in a classification (e.g., 5-digit COICOP, 5-digit NAICS, 4-digit SIC).
width	An integer vector that gives the width of each digit in x. A single value is recycled to span the longest element in x. This cannot contain NAs. The default assumes each digit has a width of 1, as in the NAICS, NAPCS, and SIC classifications.
	Lists of character vectors that give the codes/labels for each level of the classification, ordered so that moving down the list goes down the hierarchy (as made by expand_classification()).
sep	A character used to combine codes/labels across elements of The default uses ":".

Value

expand_classification() returns a list with a entry for each level in x giving the "digits" that represent each level in the hierarchy.

 $interact_classfications()$ returns a list of lists with the same structure as expand_classification().

See Also

aggregation_structure() to make a price-index aggregation structure.

20 head.piar_index

```
# 111 112 121
expand_classification(c("111", "112", "121"))
# Expanding more complex classifications
# ... if last 'digit' is either TA or TS

expand_classification(
    c("111TA", "112TA", "121TS"),
    width = c(1, 1, 1, 2)
)
# ... if first 'digit' is either 11 or 12
expand_classification(c("111", "112", "121"), width = c(2, 1))
# ... if there are delimiters in the classification (like COICOP)
expand_classification(c("01.1.1", "01.1.2", "01.2.1"), width = 2)
```

head.piar_index

Return the first/last parts of an index

Description

Extract the first/last parts of an index as if it were a matrix.

Usage

```
## S3 method for class 'piar_index'
head(x, n = 6L, ...)
## S3 method for class 'piar_index'
tail(x, n = 6L, ...)
```

Arguments

```
    x A price index, as made by, e.g., elemental_index().
    n See head()/tail(). The default takes the first/last 6 levels of x.
    ... Not currently used.
```

Value

A price index that inherits from the same class as x.

impute_prices 21

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index <- as_index(matrix(1:9, 3))
head(index, 1)
tail(index, 1)</pre>
```

impute_prices

Impute missing prices

Description

Impute missing prices using the carry forward or shadow price method.

Usage

```
shadow_price(
    x,
    period,
    product,
    ea,
    pias = NULL,
    weights = NULL,
    r1 = 0,
    r2 = 1
)

carry_forward(x, period, product)

carry_backwards(x, period, product)
```

Arguments

x A numeric vector of prices, or something that can be coerced into one.

period A factor, or something that can be coerced into one, giving the time period

associated with each price in x. The ordering of time periods follows of the

levels of period, to agree with cut().

product A factor, or something that can be coerced into one, giving the product associ-

ated with each price in x.

22 impute_prices

A factor, or something that can be coerced into one, giving the elemental aggreea gate associated with each price in x. A price index aggregation structure, or something that can be coerced into one, pias as made with aggregation_structure(). The default imputes from elemental indexes only (i.e., not recursively). weights A numeric vector of weights for the prices in x (i.e., product weights), or something that can be coerced into one. The default is to give each price equal weight. r1 Order of the generalized-mean price index used to calculate the elemental price indexes: 0 for a geometric index (the default), 1 for an arithmetic index, or -1 for a harmonic index. Other values are possible; see gpindex::generalized_mean() for details. r2 Order of the generalized-mean price index used to aggregate the elemental price indexes: 0 for a geometric index, 1 for an arithmetic index (the default), or -1 for a harmonic index. Other values are possible; see gpindex::generalized_mean() for details.

Details

The carry forward method replaces a missing price for a product by the price for the same product in the previous period. It tends to push an index value towards 1, and is usually avoided; see paragraph 6.61 in the CPI manual (2020). The carry backwards method does the opposite, but this is rarely used in practice.

The shadow price method recursively imputes a missing price by the value of the price for the same product in the previous period multiplied by the value of the period-over-period elemental index for the elemental aggregate to which that product belongs. This requires computing and aggregating an index (according to pias, unless pias is not supplied) for each period, and so these imputations can take a while. The index values used to do the imputations are not returned because the index needs to be recalculated to get correct percent-change contributions.

Shadow price imputation is referred to as self-correcting overall mean imputation in chapter 6 of the CPI manual (2020). It is identical to simply excluding missing price relatives in the index calculation, except in the period that a missing product returns. For this reason care is needed when using this method. It is sensitive to the assumption that a product does not change over time, and in some cases it is safer to simply omit the missing price relatives instead of imputing the missing prices.

Value

A copy of x with missing values replaced (where possible).

ILO, IMF, OECD, Eurostat, UN, and World Bank. (2020). *Consumer Price Index Manual: Theory and Practice*. International Monetary Fund.

See Also

price_relative() for making price relatives for the same products over time.

is.na.piar_index 23

Examples

```
prices <- data.frame(
  price = c(1:7, NA),
  period = rep(1:2, each = 4),
  product = 1:4,
  ea = rep(letters[1:2], 4)
)
with(prices, carry_forward(price, period, product))
with(prices, shadow_price(price, period, product, ea))</pre>
```

is.na.piar_index

Missing values in a price index

Description

Identify missing values in a price index.

Usage

```
## S3 method for class 'piar_index'
is.na(x)
## S3 method for class 'piar_index'
anyNA(x, recursive = FALSE)
```

Arguments

x A price index, as made by, e.g., elemental_index().

recursive

Check if x also has missing percent-change contributions. By default only index values are checked for missingness.

Value

is.na() returns a logical matrix, with a row for each level of x and a columns for each time period, that indicates which index values are missing.

anyNA() returns TRUE if any index values are missing, or percent-change contributions (if recursive = TRUE).

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

is_index

Examples

```
index <- as_index(matrix(c(1, 2, 3, NA, 5, NA), 2))
anyNA(index)
is.na(index)
# Carry forward imputation
index[is.na(index)] <- 1
index</pre>
```

```
is_aggregation_structure
```

Test if an object is an aggregation structure

Description

Test if an object is a price index aggregation structure.

Usage

```
is_aggregation_structure(x)
```

Arguments

Х

An object to test.

Value

Returns TRUE if x inherits from piar_aggregation_structure.

is_index

Test if an object is a price index

Description

Test if an object is a index object or a subclass of an index object.

Usage

```
is_index(x)
is_chainable_index(x)
is_direct_index(x)
```

Arguments

x An object to test.

Value

```
is_index() returns TRUE if x inherits from piar_index.
is_chainable_index() returns TRUE if x inherits from chainable_piar_index.
is_direct_index() returns TRUE if x inherits from direct_piar_index.
```

```
levels.piar_aggregation_structure
```

Get the levels for an aggregation structure

Description

Get the hierarchical list of levels for an aggregation structure. It is an error to try and replace these values.

Usage

```
## S3 method for class 'piar_aggregation_structure'
levels(x)
```

Arguments

x A price index aggregation structure, as made by aggregation_structure().

Value

A list of character vectors giving the levels for each position in the aggregation structure.

See Also

Other aggregation structure methods: as.matrix.piar_aggregation_structure(), update.piar_aggregation_struct weights.piar_aggregation_structure()

26 mean.piar_index

levels.piar_index

Get the levels for a price index

Description

Methods to get and set the levels for a price index.

Usage

```
## S3 method for class 'piar_index'
levels(x)
## S3 replacement method for class 'piar_index'
levels(x) <- value</pre>
```

Arguments

x A price index, as made by, e.g., elemental_index().

value A character vector, or something that can be coerced into one, giving the re-

placement levels for x.

Value

levels() returns a character vector with the levels for a price index.

The replacement method returns a copy of x with the levels in value.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

mean.piar_index

Aggregate a price index over subperiods

Description

Aggregate an index over subperiods by taking the (usually arithmetic) mean of index values over consecutive windows of subperiods.

mean.piar_index 27

Usage

```
## S3 method for class 'chainable_piar_index'
mean(
 Х,
 weights = NULL,
  ...,
 window = ntime(x),
 na.rm = FALSE,
 contrib = TRUE,
 r = 1
)
## S3 method for class 'direct_piar_index'
mean(
  Х,
 weights = NULL,
 window = ntime(x),
 na.rm = FALSE,
 contrib = TRUE,
  r = 1
)
```

Arguments

x	A price index, as made by, e.g., elemental_index().
weights	A numeric vector of weights for the index values in x, or something that can be coerced into one. The default is equal weights. It is usually easiest to specify these weights as a matrix with a row for each index value in x and a column for each time period.
	Not currently used.
window	A positive integer giving the size of the window used to average index values across subperiods. The default averages over all periods in x. Non-integers are truncated towards 0.
na.rm	Should missing values be removed? By default, missing values are not removed. Setting na.rm = TRUE is equivalent to overall mean imputation.
contrib	Aggregate percent-change contributions in x (if any)?
r	Order of the generalized mean to aggregate index values. 0 for a geometric index (the default for making elemental indexes), 1 for an arithmetic index (the default for aggregating elemental indexes and averaging indexes over subperiods), or -1 for a harmonic index (usually for a Paasche index). Other values are possible; see gpindex::generalized_mean() for details.

Details

The mean() method constructs a set of non-overlapping windows of length window, starting in the first period of the index, and takes the mean of each index value in these windows for each level of

28 merge.piar_index

the index. The last window is discarded if it is incomplete (with a warning), so that index values are always averaged over window periods. The names for the first time period in each window form the new names for the aggregated time periods.

Percent-change contributions are aggregated if contrib = TRUE by treating each product-subperiod pair as a unique product, then following the same approach as aggregate(). The number of the subperiod is appended to product names to make them unique across subperiods.

An optional vector of weights can be specified when aggregating index values over subperiods, which is often useful when aggregating a Paasche index; see section 4.3 of Balk (2008) for details.

Value

A price index, averaged over subperiods, that inherits from the same class as x.

References

Balk, B. M. (2008). Price and Quantity Index Numbers. Cambridge University Press.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index <- as_index(matrix(c(1:12, 12:1), 2, byrow = TRUE))
# Turn a monthly index into a quarterly index
mean(index, window = 3)</pre>
```

merge.piar_index

Merge price indexes

Description

Combine two price indexes with common time periods, merging together the index values and percent-change contributions for each time period.

This is useful for building up an index when different elemental aggregates come from different sources of data, or use different index-number formulas.

Usage

```
## S3 method for class 'chainable_piar_index'
merge(x, y, ...)
## S3 method for class 'direct_piar_index'
merge(x, y, ...)
```

piar_index 29

Arguments

X	A price index, as made by, e.g., elemental_index().
у	A price index, or something that can coerced into one. If x is a period-over-period index then y is coerced into a chainable index; otherwise, y is coerced into a direct index.
	Not currently used.

Value

A combined price index that inherits from the same class as x.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index1 <- as_index(matrix(1:6, 2))
index2 <- index1
levels(index2) <- 3:4
merge(index1, index2)</pre>
```

piar_index

Price index objects

Description

There are several classes to represent price indexes.

- All indexes inherit from the piar_index virtual class.
- Period-over-period indexes that can be chained over time inherit from chainable_piar_index.
- Fixed-base indexes inherit from direct_piar_index.

Details

The piar_index object is a list-S3 class with the following components:

index A list with an entry for each period in time that gives a vector of index values for each level in levels.

contrib A list with an entry for each period in time, which itself contains a list with an entry for each level in levels with a named vector that gives the additive contribution for each price relative.

30 price_relative

levels A character vector giving the levels of the index.

time A character vector giving the time periods for the index.

The chainable_piar_index and direct_piar_index subclasses have the same structure as the piar_index class, but differ in the methods used to manipulate the indexes.

price_data

Price data

Description

Sample price and weight data for both a match sample and fixed sample type index.

price_relative

Calculate period-over-period price relatives

Description

Construct period-over-period price relatives from information on prices and products over time.

Usage

```
price_relative(x, period, product)
```

Arguments

x A numeric vector of prices.

period A factor, or something that can be coerced into one, that gives the corresponding

time period for each element in x. The ordering of time periods follows the levels

of period to agree with cut().

product A factor, or something that can be coerced into one, that gives the corresponding

product identifier for each element in x.

Value

A numeric vector of price relatives, with product as names.

See Also

```
gpindex::back_period() to get only the back price.
gpindex::base_period() for making fixed-base price relatives.
carry_forward() and shadow_price() to impute missing prices.
gpindex::outliers for methods to identify outliers with price relatives.
```

```
price_relative(1:6, rep(1:2, each = 3), rep(letters[1:3], 2))
```

split.piar_index 31

split.piar_index	Split an index into groups	

Description

Split an index into groups of indexes according to a factor, along either the levels or time periods of the index.

Usage

```
## S3 method for class 'piar_index'
split(x, f, drop = FALSE, ..., margin = c("levels", "time"))
## S3 replacement method for class 'piar_index'
split(x, f, drop = FALSE, ..., margin = c("levels", "time")) <- value</pre>
```

Arguments

Х	A price index, as made by, e.g., elemental_index().
f	A factor or list of factors to group elements of x.
drop	Should levels that do not occur in f be dropped? By default all levels are kept.
	Further arguments passed to split.default().
margin	Either 'levels' to split over the levels of x (the default), or 'time' to split over the time periods of x .
value	A list of values compatible with the splitting of x, recycled if necessary.

Value

split() returns a list of index objects for each level in f. The replacement method replaces these values with the corresponding element of value.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), stack.piar_index(), time.piar_index(), window.piar_index()
```

```
index <- as_index(matrix(1:6, 2))
split(index, 1:2)
split(index, c(1, 1, 2), margin = "time")</pre>
```

32 stack.piar_index

stack.piar_index

Stack price indexes

Description

stack() combines two price indexes with common levels, stacking index values and percentchange contributions for one index after the other.

unstack() breaks up a price index into a list of indexes for each time period.

These methods can be used in a map-reduce to make an index with multiple aggregation structures (like a Paasche index).

Usage

```
## S3 method for class 'chainable_piar_index'
stack(x, y, ...)
## S3 method for class 'direct_piar_index'
stack(x, y, ...)
## S3 method for class 'chainable_piar_index'
unstack(x, ...)
## S3 method for class 'direct_piar_index'
unstack(x, ...)
```

Arguments

x A price index, as made by, e.g., elemental_index().

y A price index, or something that can coerced into one. If x is a period-overperiod index then y is coerced into a chainable index; otherwise, y is coerced into a direct index.

... Not currently used.

Value

stack() returns a combined price index that inherits from the same class as x. unstack() returns a list of price indexes with the same class as x.

Note

It may be necessary to use rebase() prior to stacking fixed-based price indexes to ensure they have the same base period.

time.piar_index 33

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), time.piar_index(), window.piar_index()
```

Examples

```
index1 <- as_index(matrix(1:6, 2))
index2 <- index1
time(index2) <- 4:6

stack(index1, index2)

# Unstack does the reverse

all.equal(
   c(unstack(index1), unstack(index2)),
   unstack(stack(index1, index2))
)</pre>
```

time.piar_index

Get the time periods for a price index

Description

Methods to get and set the time periods for a price index.

Usage

```
## S3 method for class 'piar_index'
time(x, ...)

time(x) <- value

## S3 replacement method for class 'piar_index'
time(x) <- value

## S3 method for class 'piar_index'
start(x, ...)

## S3 method for class 'piar_index'
end(x, ...)</pre>
```

Arguments

```
    x A price index, as made by, e.g., elemental_index().
    ... Not currently used.
    value A character vector, or something that can be coerced into one, giving the replacement time periods for x.
```

Value

time() returns a character vector with the time periods for a price index. start() and end() return the first and last time period. ntime() returns the number of time periods, analogous to nlevels().

The replacement method returns a copy of x with the time periods in value.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), window.piar_index()
```

```
update.piar_aggregation_structure

Update an aggregation structure
```

Description

Price update the weights in a price index aggregation structure.

Usage

```
## S3 method for class 'piar_aggregation_structure'
update(object, index, period = end(index), ..., r = 1)
```

Arguments

object	A price index aggregation structure, as made by aggregation_structure().
index	A price index, or something that can be coerced into one. Usually an aggregate price index as made by aggregate().
period	The time period used to price update the weights. The default uses the last period in index.
	Not currently used.
r	Order of the generalized mean to update the weights. The default is 1 for an arithmetic index.

Value

A copy of object with price-updated weights using the index values in index.

See Also

aggregate() to make an aggregated price index.

Other aggregation structure methods: as.matrix.piar_aggregation_structure(), levels.piar_aggregation_structure() weights.piar_aggregation_structure()

Examples

```
# A simple aggregation structure
#
#
      11
                  12
# |---+
                  # 111 112
                  121
                   (4)
# (1)
           (3)
aggregation_weights <- data.frame(</pre>
  level1 = c("1", "1", "1"),
 level2 = c("11", "11", "12"),
 ea = c("111", "112", "121"),
  weight = c(1, 3, 4)
)
pias <- as_aggregation_structure(aggregation_weights)</pre>
index <- as_index(</pre>
 matrix(1:9, 3, dimnames = list(c("111", "112", "121"), NULL))
)
weights(pias, ea_only = FALSE)
weights(update(pias, index), ea_only = FALSE)
```

weights.piar_aggregation_structure

Get the weights for an aggregation structure

Description

Get and set the weights for a price index aggregation structure.

Usage

```
## S3 method for class 'piar_aggregation_structure'
weights(object, ..., ea_only = TRUE, na.rm = FALSE)
weights(object) <- value
## S3 replacement method for class 'piar_aggregation_structure'
weights(object) <- value</pre>
```

Arguments

object	A price index aggregation structure, as made by aggregation_structure().
	Not currently used.
ea_only	Should weights be returned for only the elemental aggregates (the default)? Setting to FALSE gives the weights for the entire aggregation structure.
na.rm	Should missing values be removed when aggregating the weights (i.e., when ea_only = FALSE)? By default, missing values are not removed.
value	A numeric vector of weights for the elemental aggregates of object.

Value

weights() returns a named vector of weights for the elemental aggregates. The replacement method replaces these values without changing the aggregation structure. If ea_only = FALSE then the return value is a list with a named vector of weights for each level in the aggregation structure.

See Also

            112
                     121
# (1)
            (3)
                      (4)
aggregation_weights <- data.frame(</pre>
 level1 = c("1", "1", "1"),
level2 = c("11", "11", "12"),
ea = c("111", "112", "121"),
  weight = c(1, 3, 4)
)
pias <- as_aggregation_structure(aggregation_weights)</pre>
# Extract the weights
weights(pias)
# ... or update them
weights(pias) <- 1:3
weights(pias)
```

window.piar_index 37

window.piar_index

Index window

Description

Extract and replace index values over a window of time periods.

Usage

```
## S3 method for class 'piar_index'
window(x, start = NULL, end = NULL, ...)
## S3 replacement method for class 'piar_index'
window(x, start = NULL, end = NULL, ...) <- value</pre>
```

Arguments

X	A price index, as made by, e.g., elemental_index().
start	The time period to start the window. The default in the first period of \boldsymbol{x} .
end	The time period to end the window. The default is the last period of x.
	Not currently used.
value	A numeric vector or price index.

Value

window() extracts a price index over a window of time periods that inherits from the same class as x. The replacement method replaces these with value.

See Also

```
Other index methods: [.piar_index(), aggregate.piar_index(), as.data.frame.piar_index(), chain(), contrib(), head.piar_index(), is.na.piar_index(), levels.piar_index(), mean.piar_index(), merge.piar_index(), split.piar_index(), stack.piar_index(), time.piar_index()
```

```
x <- as_index(matrix(1:9, 3))
window(x, "2")
window(x, "2") <- 1
x</pre>
```

38 [.piar_index

Francisco Francisco index values
[.piar_index

Description

Methods to extract and replace index values like a matrix.

Usage

```
## S3 method for class 'piar_index'
x[i, j, ...]
## S3 replacement method for class 'piar_index'
x[i, j, ...] <- value</pre>
```

Arguments

X	A price index, as made by, e.g., elemental_index().
i, j	Indices for the levels and time periods of a price index. See details.
• • •	Not currently used.
value	A numeric vector or price index. See details.

Details

The extraction method treats x like a matrix of index values with (named) rows for each level and columns for each time period in x. Unlike a matrix, dimensions are never dropped as subscripting x always returns an index object. This means that subscripting with a matrix is not possible, and only a "submatrix" can be extracted. As x is not an atomic vector, subscripting with a single index like x[1] extracts all time periods for that level.

The replacement method similarly treat x like a matrix. If value is an index object with the same number of time periods as x[i, j] and it inherits from the same class as x, then the index values and percent-change contributions of x[i, j] are replaced with those for the corresponding levels of value. If value is not an index, then it is coerced to a numeric vector and behaves the same as replacing values in a matrix. Note that replacing the values of an index will remove the corresponding percent-change contributions (if any). Unlike extraction, it is possible to replace value in x using a logical matrix or a two-column matrix of indices.

Value

A price index that inherits from the same class as x.
